# Icelandic epidemic

- Identified April 2010
- Approximately 80,000 horses affected
- Morbidity: 100%
  - Almost the entire horse population was sensitive to the infection indicating a new infectious agent
  - Lack of specific immunity
- Mortality: very low
- Incubation time: 1 - 4 weeks
  - depending on the infectious load
- Zoonoses
  - three cases including miscarriage
- Export of horses stopped
  - May 2010 to Jan 2011

# Microbiological investigations

- Extensive virological investigations
  - Institute for Experimental Pathology at Keldur, Iceland
  - National Veterinary Institute in Uppsala, Sweden
  - Institute of Virology, Justus-Liebig-Universität in Giessen, Germany
- No viruses could be detected as a possible primary cause of the outbreak
- *Streptococcus equi* subsp. *equi*
  - Negative by culture and PCR tests
- Almost all clinical cases were positive for *Streptococcus equi* subsp. *zooepidemicus*

# Illumina sequencing

Random array of DNA clusters

- 3 multiplex libraries of 288 strains
- Sequence mapped to a reference genome, H70
- Core and accessory genome
  - Core SNPs used to generate a phylogeny with other sequenced *S. zooepidemicus* isolates

# Main Icelandic clades

Clade 4

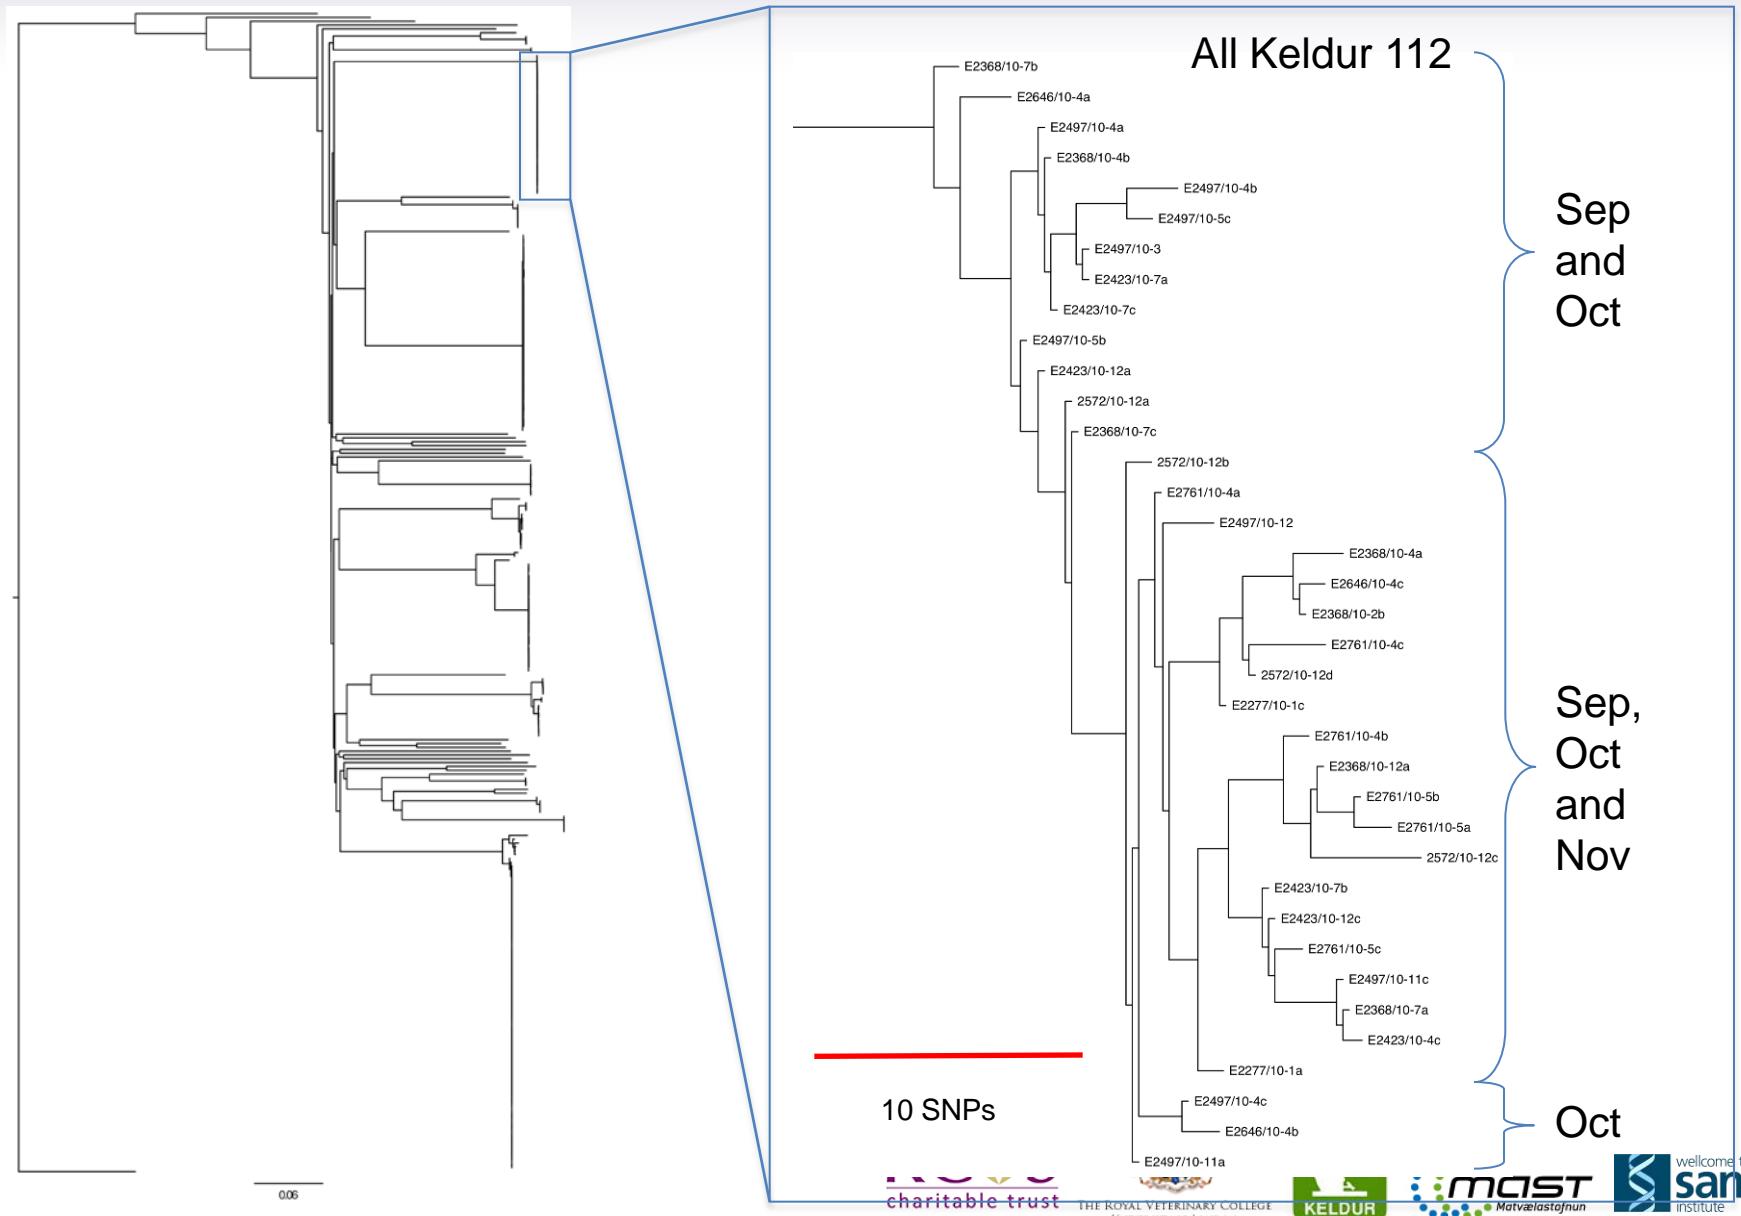

Clade 3

Clade 2

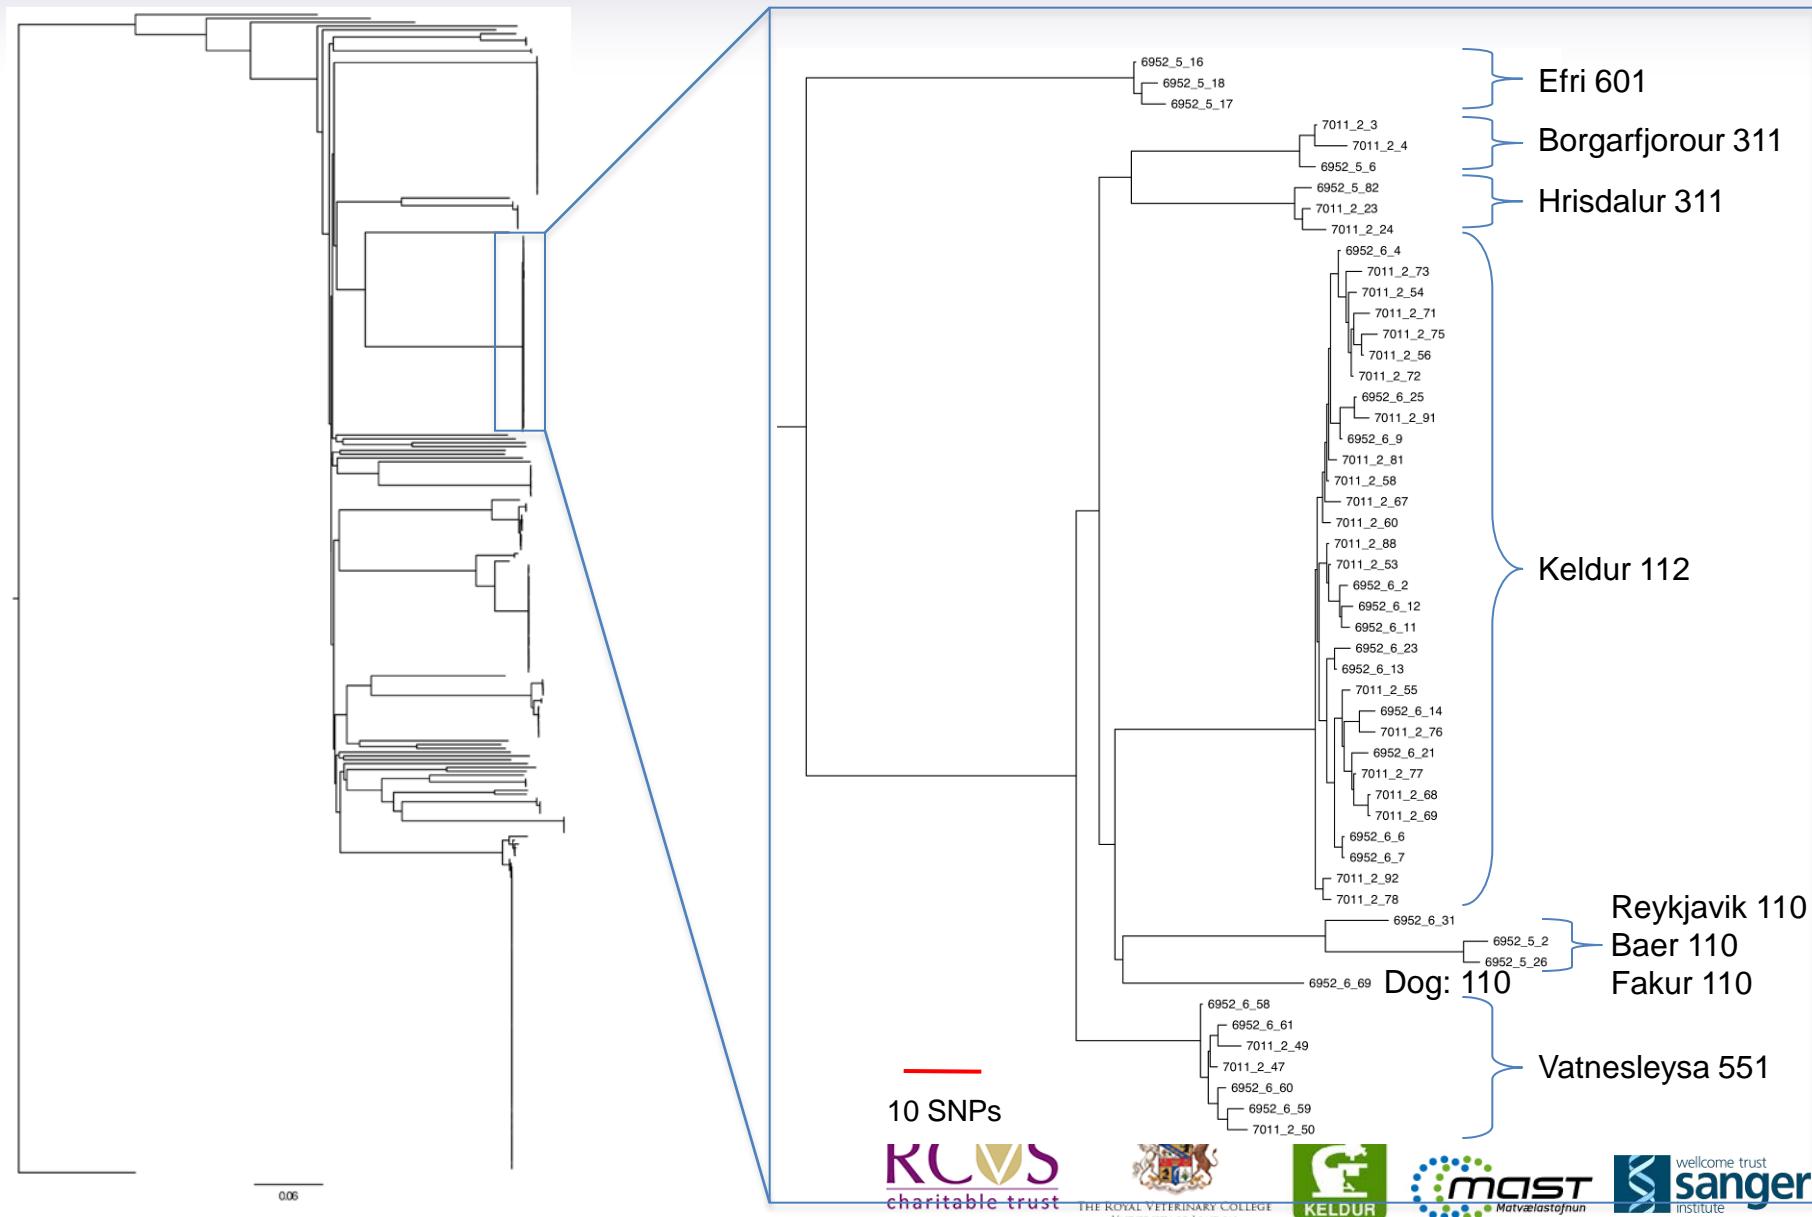

Clade 1

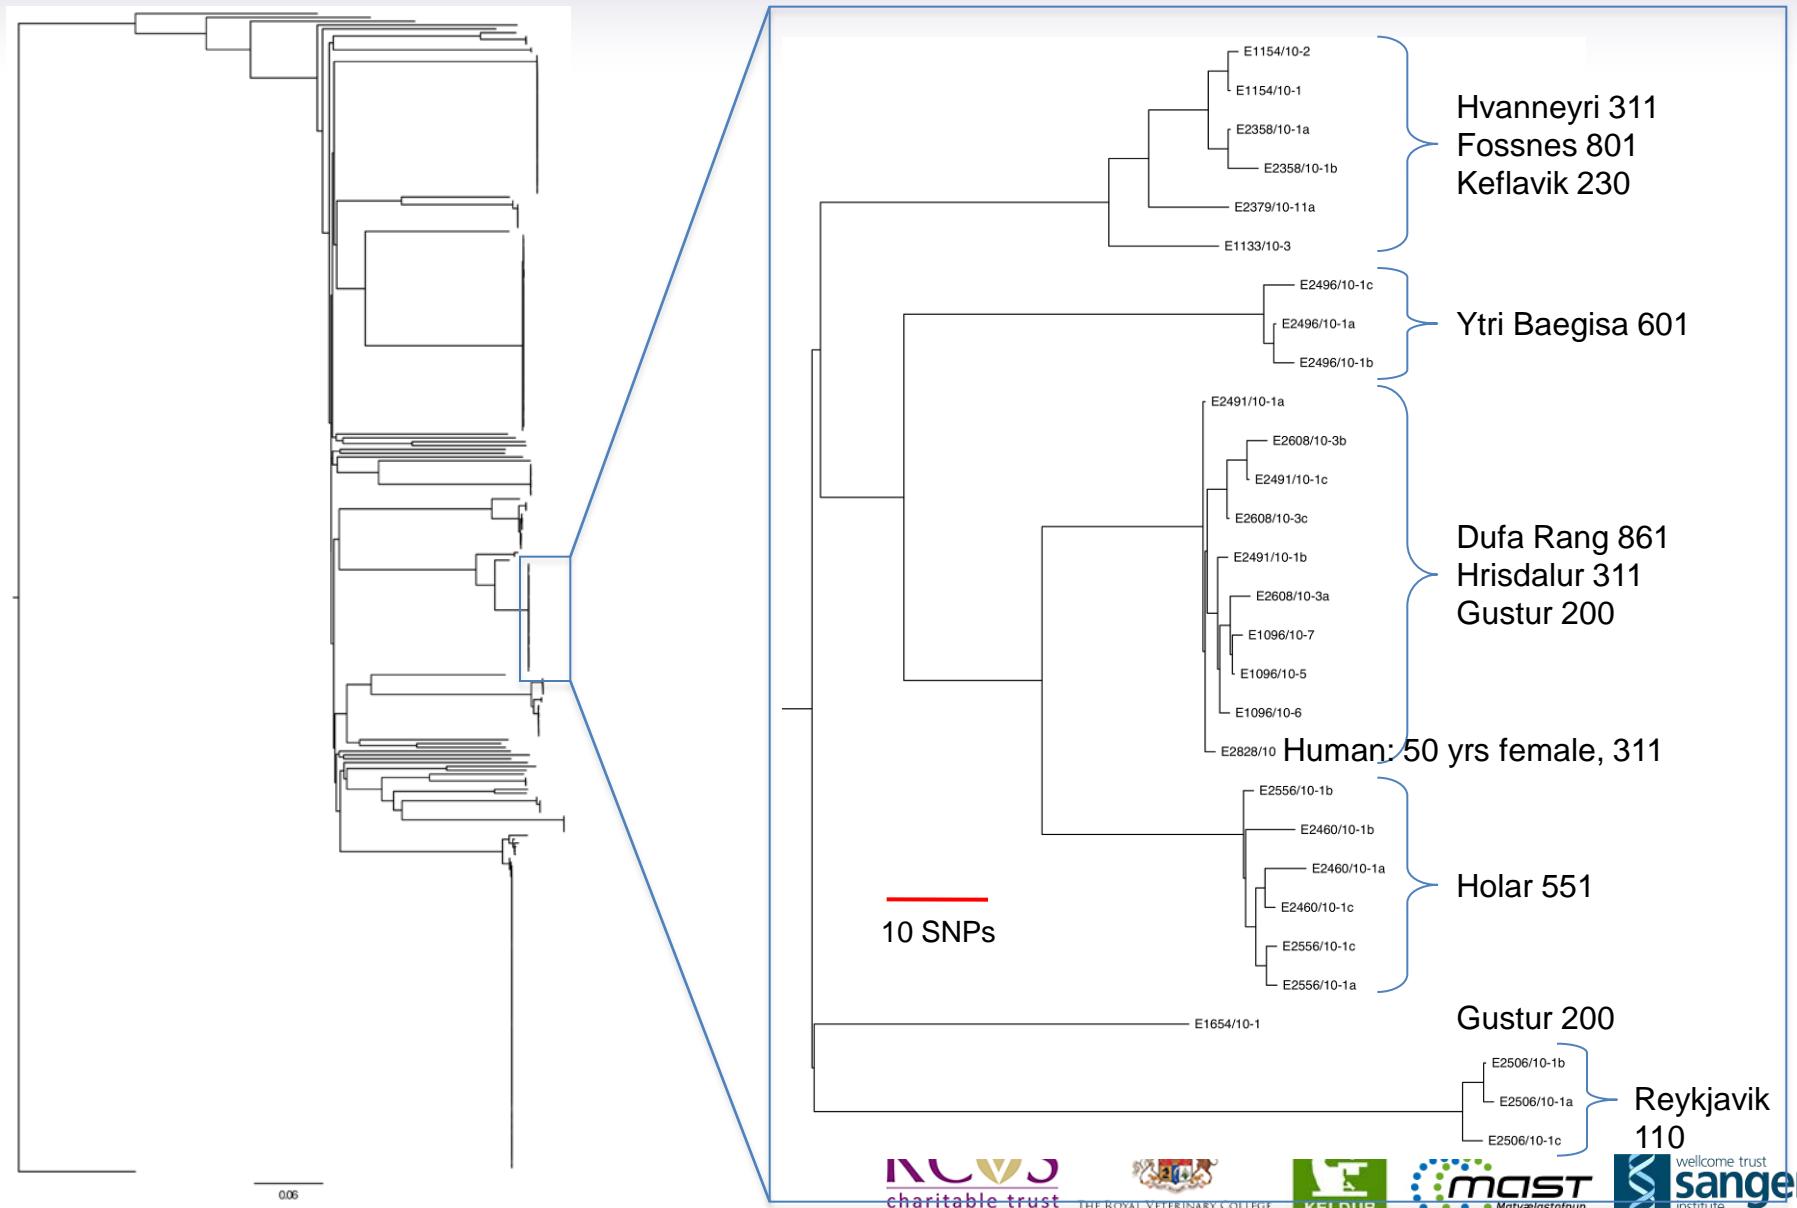

# Clade 4

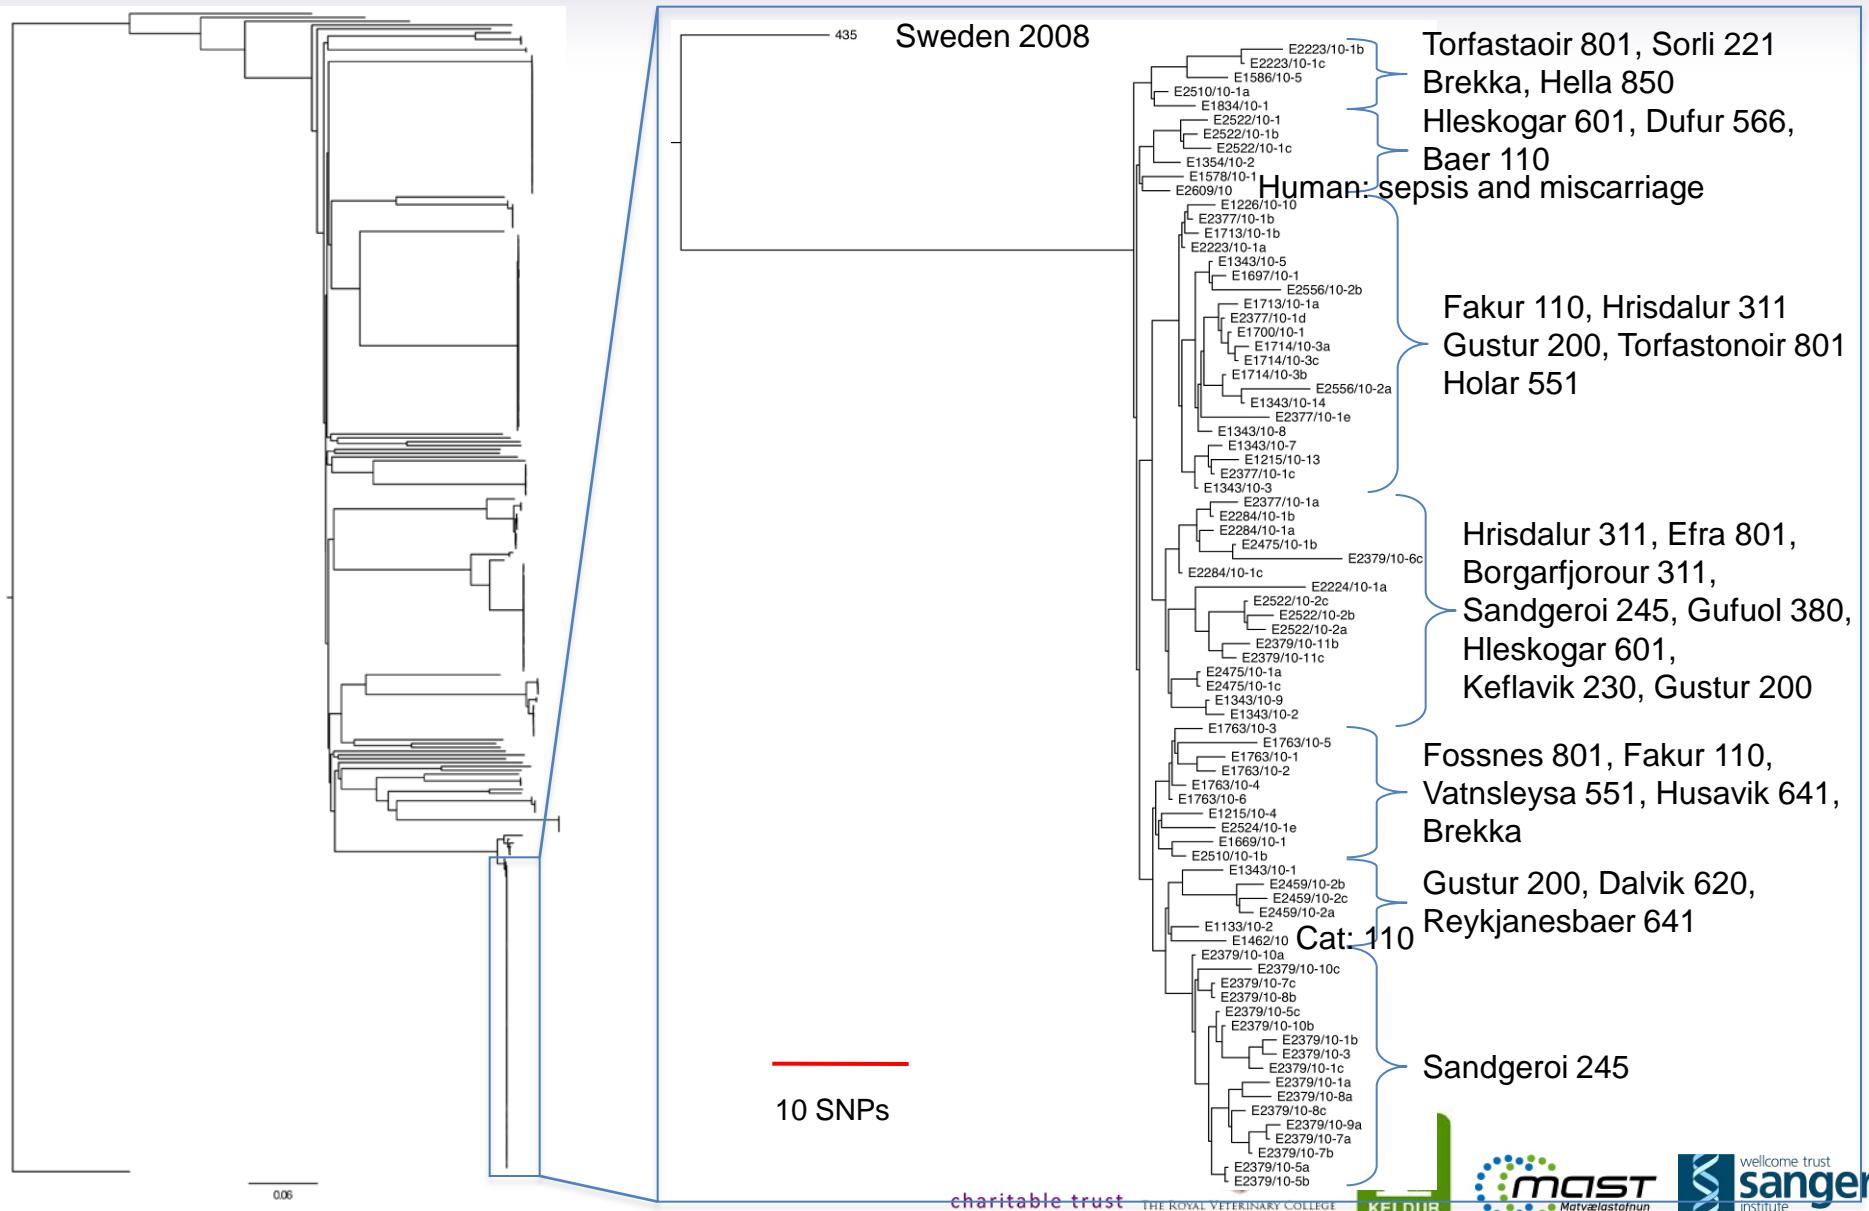

# Clade 3 – ST-248

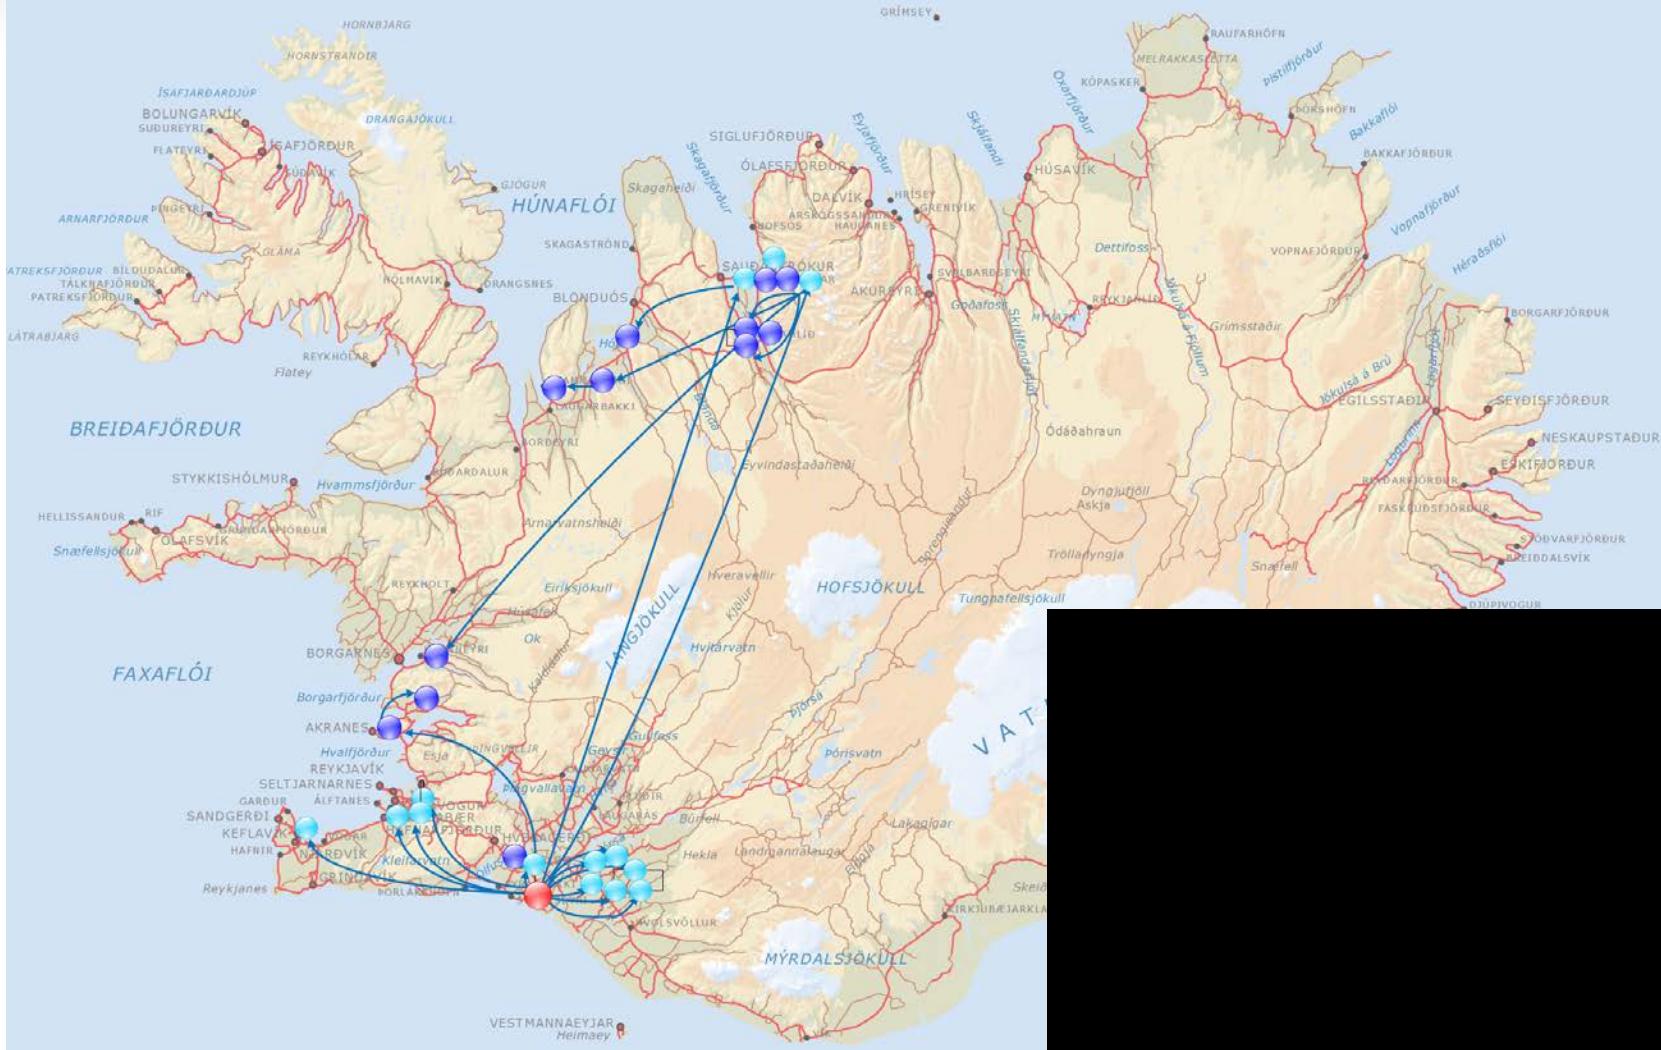

# Clade 2 – ST-246

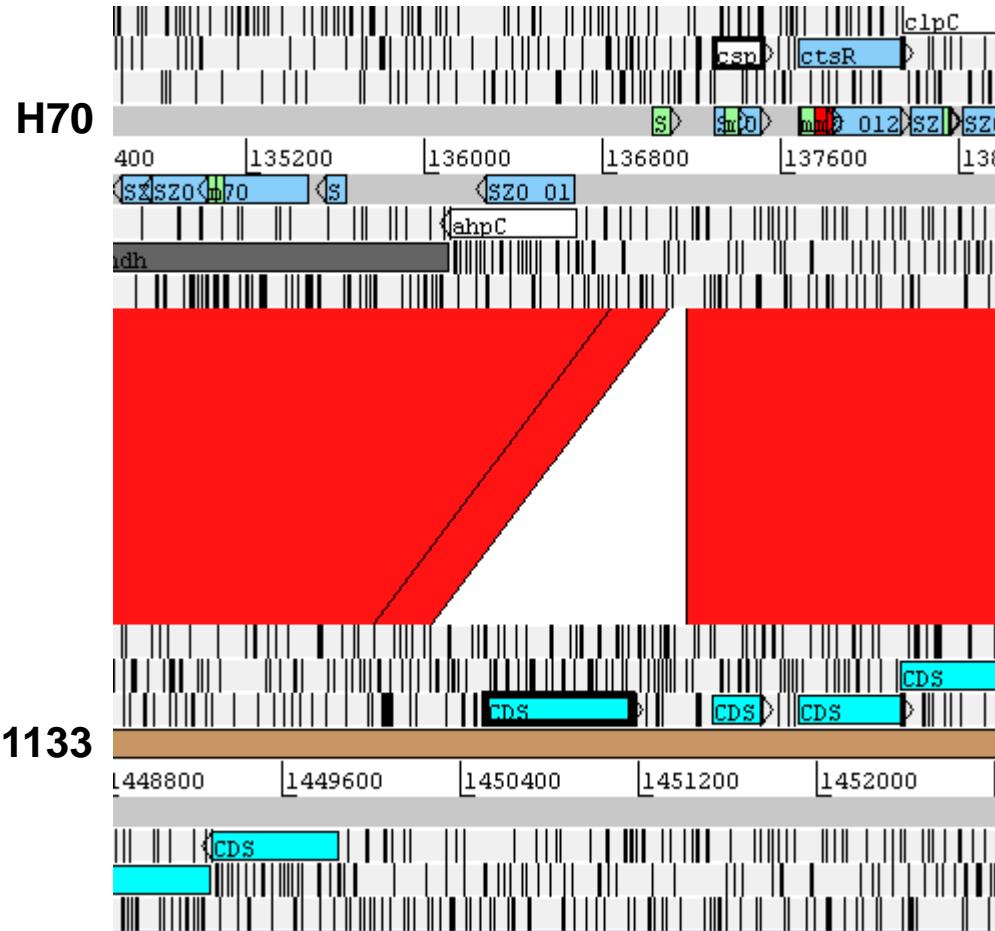

# Clade 1- ST-209

# Network analysis (Feb/Mar 2010)

# ST-209 genome features

- Variant of SzeF
- Increases coughing and transmission??

# *S. zooepidemicus* – an agile pathogen

- Causes disease in a huge variety of hosts
  - Adapted to horses
- Flexible and opportunistic
  - Usually sub-clinical
  - Non-equine disease can be severe
- Highly diverse
  - Constantly probing pathogenic boundaries
- Can we prevent it?
  - Vaccination
    - Needs to be broad coverage of strains
